When the your gots rough and your
14-ton jeep frame cracks and breaks around
the rear spring-hangers, a little reinforcement will probably prevent a repeat performance. After Sgt. Cecil Crocker saw a bunch of
his Signal Corps outfit's jeeps in North Africa limping home with broken frames, he knocked out a reinforcing plate to knock out the trouble.

You can do it, too, with the aid of the salon photographs on these pages (showing the job on a Willys).

Then, when the last bolt's in place, you'll have approximately the same sturdy frame reinforcement as the manufacturers (Willys and Ford) are now giving 1/4-tons on the assembly line. This recent production change reinforces the frame at the same points and with just about the same plates as those used by 5gt. Crocker. Looks like he started something.

Incidentally, some later-vintage jeeps have a reinforcing plate on the inside of the frame channel at the spring hanger—but they can stand this extra reinforcement, too, when the going really gets rugged.

3/16" TO 1/6" TIDOS

them, from a rap) to the shape and dimensions shown here. While the state holes with a 36" shill.

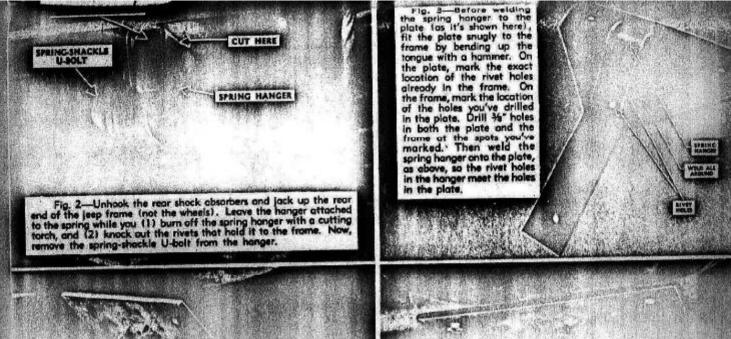

Fig. 5—Bolt the reinforcing plate to the frame with 36" bolts—these go through the original rivet holes in the frame and through the three new holes you've drilled. In this picture, the rear end of the frame's still jacked up and the shock absorber's still dangling. After the job is done—on both sides of your jeep—just let the jack down and hook up the shocks.
